

ECC006 Homework Assignment #7 — Answers

Badir Alhaj Younis - 20215054 - NEU Software Engineering

1. How would you link to the named fragment #jobs on employ.html from the home page?

Answer: (a) `<a href="employ.html#jobs">Jobs</a>`

To link to a fragment on another page, combine the page path with #fragment in the href.

2. Which pseudo-element generates content that precedes an element?

Answer: (b) `:before`

`:before` (or `::before`) inserts generated content before an element's content.

3. Which of the following is a mobile web design best practice?

Answer: (c) Configure a single-column page layout.

Single-column layouts are ideal for small screens. Multi-column, embedded text in images, and avoiding lists are all bad practices for mobile.

4. Find the Error — The navigation area should display on the RIGHT side:

Answer: Change `nav { float: left }` to `nav { float: right }`

`/* BEFORE (wrong): */`

```
nav { float: left; width: 120px; }  
main { padding: 20px 150px 20px 20px; }
```

`/* AFTER (correct): */`

```
nav { float: right; width: 120px; }  
main { padding: 20px 20px 20px 150px; }
```

`float:left` puts the nav on the left. To move it right, use `float:right`. Also swap the main padding so the left side has the large value for content space.

Web Research Summary — Accessibility & Mobile Web Design (W3C WAI/Mobile):

Web accessibility and mobile web design share many important principles, as highlighted by the W3C's "Web Content Accessibility and Mobile Web" document. Developers who build accessible websites are simultaneously building sites that work better on mobile devices, and vice versa. Key areas of overlap include:

- (1) Single-column layouts — recommended for mobile screens and also benefit screen reader users by providing a clear, linear reading order.
- (2) Alternative text for images — helps visually impaired users and also benefits mobile users on slow connections where images may not load.
- (3) Clear headings and structure — assistive technologies rely on proper heading hierarchy, and mobile users benefit from scannable, well-organized content.
- (4) Avoiding text embedded in images — both screen readers and mobile devices struggle to process text within images.
- (5) Keyboard and touch navigation — designing for keyboard accessibility also improves touch-based navigation on mobile devices.

Web developers can support both goals simultaneously by adopting a mobile-first and accessibility-first mindset from the start of a project. Using semantic HTML5 elements (such as `<nav>`, `<main>`, `<aside>`), ensuring sufficient color contrast, providing scalable fonts, and designing touch-friendly targets all contribute to an inclusive experience for users regardless of device or ability. The convergence of these two disciplines demonstrates that good design is inherently accessible and responsive.
